SEQUENTIAL UNIQUE MARKING

BACKGROUND OF THE INVENTION

[0001] Field of the Invention: The current invention relates generally to marking semiconductor dice having integrated circuits (ICs) and, more specifically, to a system for uniquely marking exterior surfaces of semiconductor dice in lots.

[0002] State of the Art: In conventional semiconductor device fabrication processes, a number of distinct semiconductor devices, such as memory chips or microprocessors, are fabricated on a semiconductor substrate, such as a silicon wafer. Each semiconductor wafer has a plurality of integrated circuit semiconductor die (IC) arranged in rows and columns with the periphery of each IC being substantially rectangular or square. After the desired structures, circuitry, and other features of each of the semiconductor devices have been fabricated upon the semiconductor substrate, the substrate is typically singulated to separate the individual semiconductor devices from one another.

[0003] While semiconductor die may carry information on the active surface thereof regarding the manufacturer, specifications, etc., such information cannot be easily read without the use of optical devices. Therefore, subsequent to the wafer dicing process, individual semiconductor die are commonly subjected to a marking process wherein various easily read information is placed on the backside or inactive side of the semiconductor die for purposes of corporate identity, product differentiation and counterfeit protection.

[0004] Currently, the preferred method of marking packaged semiconductor die is using a laser beam. Lasers are used to mark semiconductor die with a manufacturer's logo, as well as alphanumeric marks and bar codes specifying the company's name, a part or serial number, or other information such as lot or die location. In particular, lasers have become especially useful in marking high production items such as bare or packaged semiconductor die. The high speed and precision of laser marking makes their use highly desirable for high throughput automated processes. Unlike the previously utilized technique of ink stamping, laser marking is very fast, requires no curing time, produces a consistently high quality mark, and can take place at any point in the manufacturing process.

[0005] Traditionally, semiconductor devices are marked as a group of 25 to as many as 50 devices having similar parameters. Singulated semiconductor devices are characterized for compliance with certain criteria in order to determine their suitability, or lack thereof, for different potential uses. For example, devices may be separated based on operating speed wherein devices performing above a particular speed are placed in one group while devices functioning at a slower speed are placed into a different group. Carriers such as tubular magazines or bins 200 can be used to physically separate groups of devices 250 (FIG. 3). However, these carriers are unsuitable for recently developed semiconductor packages that are much-reduced in size, thickness and dimensions of individual features, such as leads for external connection to higher-level packaging.

[0006] One example of such state-of-the-art semiconductor device packages is a thin plastic package configuration identified as a Thin Small Outline Package, or TSOP. Another is a Thin Quad Flat Pack, or TQFP. By way of comparison, such packages are dimensioned with a total package thickness, excluding lead fingers, of less than about one-half the thickness of a conventional plastic Small Outline J-lead package, or SOJ. These newer semiconductor device packages, with their smaller dimensions and more fragile components, are much more susceptible to inadvertent damage in handling than prior package designs and, at best, are only marginally robust enough for handling in tubular magazines. As a result, the industry has gravitated to processing such relatively delicate semiconductor packages in batches carried in recesses of rectangular trays, one example of which are so-called JEDEC trays 100 (FIG. 1). Other, even smaller semiconductor packages under current development and most recently introduced to the market include so-called "chip scale" semiconductor packages. These packages, having dimensions approximating those of a bare semiconductor die itself and employing extremely minute external connection elements, also are desirably handled in trays.

[0007] As stated, groups or lots of semiconductor devices or bare semiconductor die consist of a particular device type and are selected to meet customer or industry standard specification. After sorting, semiconductor die are typically marked as a group such that all semiconductor die receive the same mark. Semiconductor die generally undergo an array of

testing during the manufacturing process and groups of semiconductor dice can be tracked through the fabrication, probe, assembly and test steps. However, this so called lot-based manufacturing has several limitations including that it is inefficient, expensive, unreliable and it is impossible to achieve truly unique marking of semiconductor devices.

[0008] As a lot of semiconductor dice bearing the same identification number passes through manufacturing, data associated with the lot is generated and stored in association with the lot number. It is critical to track all semiconductor die individually in a particular order so that test results can be correlated with the proper die. However, manufacturers must balance the benefit of identifying problems within individual semiconductor die with the fact that maximum efficiency is achieved when a large number of semiconductor dice are tested in succession and problems are addressed only after the testing is complete. Accordingly, semiconductor dice are tested and results are recorded sequentially. To maintain accurate results, semiconductor die must be placed and stored in carrier tubes in the identical order. The potential for error in lot-based manufacturing is very high as one misplaced semiconductor die or carrier results in inaccurate data association.

[0009] United States Patent 5,856,923 to Jones et al. discloses a method of continuous non-lot based integrated circuit manufacturing. In this process, each device from a mixed lot is provided either a substantially unique fuse ID code or marked on the lead frame with a substantially unique ID code. (United States Patent 6,049,624 Wilson et al.). The devices are processed and process related data is generated for each individual device. Data relating to the particular device, rather than the entire lot, is stored in association with the substantially unique ID code.

[0010] United States Patent 6,049,624 to Wilson et al. further discloses marking carrier trays or storage shelves with an ID code and storing the carrier tray ID code in association with the ID code for semiconductor die. Semiconductor die can be retrieved by lot number from the shelves or carrier trays.

[0011] It would be an improvement in the art to develop a technique of in-tray mapping and sequential unique marking of packaged semiconductor devices or bare semiconductor die that eliminates the need for them to be pre-sorted

BRIEF SUMMARY OF THE INVENTION

[0012] One embodiment of the present invention includes a method of sequential unique marking comprising providing a multi-die handling device with a plurality of packaged semiconductor devices or bare semiconductor die therein, reading an ID code on the multi-die handling device, retrieving a tray map file corresponding to the ID code, determining a tray matrix of the multi-die handling device, retrieving data from the tray map file, the data comprising unique characters correlating to each semiconductor device or semiconductor die of the plurality of semiconductor devices or semiconductor dice and marking each semiconductor device or semiconductor die with the data.

[0013] Another embodiment of the present invention includes a method of culling semiconductor devices or bare semiconductor dice from a reject bin. The method includes retrieving a plurality of semiconductor devices or bare semiconductor die from a reject bin, providing a plurality of multi-die handling devices having a plurality of pocket locations and assigning each multi-die handling device an ID code. Each semiconductor device or bare semiconductor die is placed in a pocket location of the plurality of pocket locations. The semiconductor devices or bare semiconductor die are tested and a tray map file comprising test data is generated. The tray map file is stored in association with the ID code of the multi-die handling device. The method further includes reading the ID code on a multi-die handling device, retrieving the tray map file corresponding to the ID code, determining a tray matrix of the multi-die handling device, retrieving unique test data from the tray map file and marking each semiconductor device or bare semiconductor die of said plurality of semiconductor devices or bare semiconductor dice with the corresponding test data.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

[0014] FIG. 1 illustrates a common JEDEC tray for carrying multiple devices;

[0015] FIG. 2 is a flow chart of sequential unique marking of the present invention;
and

[0016] FIG. 3 illustrates a perspective view of a tray shuttle including a magazine carrier.

DETAILED DESCRIPTION OF THE INVENTION

[0017] Tray mapping is the logical assignment of pocket locations within the boundaries of a multi-die handling device, such as a JEDEC tray 100 shown in drawing FIG.

1. The purpose of tray mapping is to establish a correlation between the location of devices in a tray and the tray itself. This positional relationship of devices in a tray is important as it directly relates to test result data created by in-tray test equipment.

[0018] As shown in drawing FIG. 1, a JEDEC tray 100 consists of pocket locations 110 in rows and columns (X and Y-axis coordinates). Each pocket location 110 is assigned a unique coordinate number based on its X and Y-axis coordinates. In the example shown, pocket locations 110 receive a unique whole number (*i.e.*, 1.0, 2.0, 3.0) corresponding to its location along the X axis and a unique fractional number (*i.e.*, 0.1, 0.2, 0.3) corresponding to its location along the Y axis. While the current invention is described using a JEDEC tray 100, it will be understood by those of skill in the art that the invention is applicable to any multi-die handling device including multi-die handling devices having vertical carrier capabilities (*e.g.*, a multi-die handling device that can store die along X, Y and Z coordinates). Further, as used herein, the terms “tray”, “carrier” and “multi-die handling device” are used interchangeably.

[0019] It will be further understood by those having skill in the field of this invention that the present invention is applicable to any IC device, including Dynamic Random Access Memory (DRAM) IC's, Static Random Access Memory (SRAM) IC's, Synchronous DRAM (SDRAM) IC's, processor IC's, Single In-Line Memory Modules (SIMM's), Dual In-Line Memory Modules (DIMM's), and other Multi-Chip Modules (MCM's).

[0020] The presently claimed invention includes a method of quickly placing unique characters, as well as non-unique characters, on every semiconductor device in a tray matrix. Preferably, semiconductor devices are marked by a laser having a six-inch mark field which allows a standard JEDEC tray 100 to be marked in half the amount of time. Examples of unique characters include, but are not limited to, test data extracted from a tray map file. For example, four characters [2 bytes in Hex (FAFA)] representing test data unique to each semiconductor device in the tray.

[0021] Examples of non-unique characters include, but are not limited to, semiconductor device data (dynamic objects) and graphics (static objects) common to all the semiconductor devices in the tray. Further examples of non-unique characters include, but are not limited to, date code, semiconductor device type, country code, and company logo.

[0022] A tray map file, according to the present invention, may include a file including test data collected during in-tray testing of semiconductor die. By way of example, semiconductor devices that do not meet specific criteria during initial processing are often discarded into reject bins and certain manufacturers are increasingly relying upon salvaging semiconductor devices from reject bins. All of the previously rejected semiconductor devices must be tested to characterize the devices and determine their suitability for use. Preferably, these semiconductor devices, from mixed lots and with unknown parameters, are placed in a multi-die handling device and tested "in-tray". Test results are preferably stored as data in a tray map file wherein the data is stored in association with a particular pocket location. Each carrier or multi-die handling device is assigned an optically readable ID code and the tray map file is stored in association with the ID code.

[0023] Illustrated in drawing FIG. 2 is a flow-chart of sequential unique marking of the current invention. The process of sequential unique marking can take place either before or after packaging of semiconductor die. In step 10, the optically readable ID code, or barcode, on the multi-die handling device or tray is read and the corresponding tray map file is retrieved. The tray matrix and the number of cells, or pocket locations, is determined in step 20. For example, in the JEDEC tray 100 shown in drawing FIG. 1, the matrix includes rows and columns as shown by the X-axis and Y-axis. The number of cells is equal to the number of rows times the number of columns. Those skilled in the art will appreciate that the step of determining the tray matrix may include a third Z- axis.

[0024] Data from the tray map file is retrieved in step 30. As stated above, the tray map file preferably includes the results, or device parameters, of in-tray testing. The device in the current cell is marked with the tray map data in step 40. Various laser marking methods are known in the art. The methods of efficiently laser marking singulated semiconductor devices as described in United States Patents 5,986,235 and 5,937,270, and

assigned to the assignee of the presently claimed invention, are incorporated herein by this reference. Further, United States patent application Serial No. 09/217,040, filed December 21, 1998, assigned to the assignee of the presently invention, and hereby incorporated herein by this reference, discloses a laser marking system for dice carried in trays and method of operation.

[0025] After the semiconductor device is marked, it is determined whether the current cell is the last cell on the tray in step 50. If there is another cell on the tray, the process moves to the next cell on the tray in step 60 and steps 30 through 50 are repeated. When the last cell on the tray is reached, it is determined whether any other trays exist in step 70. If additional trays are present, steps 10 through 50 are repeated. When the last tray is reached, sequential unique marking is complete 90.

[0026] At the end of the process described, all of the semiconductor devices in a multi-die handling devices receive sequential unique markings using one mark command. One advantage of the present invention is the elimination of the need to pre-sort devices before marking. By marking devices with test data, preferably related to device parameters, truly unique marking is achieved. Further, the presently claimed invention creates a “virtual binning” of devices, wherein the parameters of each semiconductor device are known and associated with a specific location within a multi-die handling device.

[0027] Although the foregoing description contains many specifics, these should not be construed as limiting the scope of the present invention, but merely as providing illustrations of some of the presently preferred embodiments. Similarly, other embodiments of the invention may be devised which do not depart from the spirit or scope of the present invention. Features from different embodiments may be employed in combination. The scope of the invention is, therefore, indicated and limited only by the appended claims and their legal equivalents, rather than by the foregoing description. All additions, deletions and modifications to the invention as disclosed herein which fall within the meaning and scope of the claims are to be embraced thereby.
